

# Monopoly

# Goals

- Define and look at the effects of monopoly.
- Use as a general model for what happens when there is market power.
- Get through the ugliest graphs in EC 201

# Monopoly Key Assumptions

The same as perfect competition except:

- There is only one seller
- The seller engages in price setting behavior.
  - In PC, firms observe price and then choose quantity to maximize profits.
  - In Monopoly, firms observe demand and then choose quantity and let the price adapt.
- No entry or exit. Technically you only need no entry but no exit makes this simpler.

# Monopolies are

Don't think of monopolies as being globe spanning huge corporations. Monopoly power often simpler.

- The only gas station in a small geographically isolate town.
- The only provider of a drug needed for a medical condition.
- Local newspaper/radio or TV station for local news.
- Sometimes the best answer to a problem, but we regulate those.

# How can I get one?

- Geographic isolation
- Barriers to entry
- Control of a unique resource – Rich minerals, a face, knowledge
- Government grants it to you – franchise
- Intellectual Property – Patent, copyright.
- Large ~~economy~~ of scale – like natural gas distribution
- Network externalities – non-standard connectors

# What is different About the Analysis?

- In perfect competition,  $MR = AR = P = D_{firm}$ .
- In monopoly (Single price), MR splits off.
- Because of no entry or exit – no long-run analysis on extensive margin. Plenty happens on intensive but wait till EC 311/415 for that.

# Marginal Revenue

The additional revenue from selling one more unit.

- This is price in perfect competition.
- $MR < Price$  in monopoly because to sell one more, you must reduce price on all units sold.

# Math For Calculus Folks

Assume a linear demand,  $P = P_0 - \alpha q$

$$R(q) = Pq = (P_0 - \alpha q)q = P_0q - \alpha q^2$$

The derivative of revenue is marginal revenue

$$MR(q) = \frac{\partial}{\partial q} R(q) = P_0 - 2\alpha q$$

Same intercept but twice as steep.

# Build MR Graphically

# Key Takeaways

- Same intercept but twice as steep.
- Marginal revenue can be negative.
- Revenue, not profit, is maximized when  $MR = 0$ .

# Steps

These are the same as Perfect Competition.

- Find  $q^*$  where  $MC = MR$
- Start at  $q^*$  go to AC and hang a left.
  - That is  $AC^*$ .
  - Box is Total Cost,  $TC^* = AC^* q^*$
- Start at Start at  $q^*$  go to  $AR = D_{firm}$  and hang a left.
  - That is  $AR^*$ .
  - Box is Total Revenue,  $TR^* = AR^* q^*$
- Little box on top is profit.

# Monopoly Graphs

1. Find  $Q^*$  where  $MR = MC$ .

2. Start at  $Q^*$  and go up to AC and then left, that is  $AC^*$ .

3. Start at  $Q^*$  and go up to AR and then left. That is  $AR^*$ .

1.  $Q^*$
2.  $AC^*$
3.  $AR^*$

# Why Monopoly is Bad

- Price and quantity effects
  - Price is higher
  - Less is sold
- Welfare Effects
  - DWL
  - Reduction in CS
- Long-run Effects
  - Price and cost above marginal cost

## Price and quantity effects

Labeled lines on graph.

1.  $MC$  is the supply for competitive firms.

2.  $Q^M < Q^{P.C.}$

3.  $P_M > P^{P.C.}$

## Welfare Effects

## Long-run Effects

## But, sometimes we need a monopoly

Minimize fixed costs for things like local electricity and natural gas distribution.

- Why have two conduits or service heads to your house when you only need one.
- In this case the monopolist has lower costs but still charges higher prices.
- We regulate these firms. This is in EC 437 Public Utility Economics.

# Example

- We call this a natural monopoly
- Fixed cost but MC is constant  $C(q) = F + \beta q$ .
- Cost of one firm to produce  $F + \beta q$
- Cost of two firms  $(F + \beta q/2) + (F + \beta q/2) = 2F + \beta q$
- Twice the fixed cost

## Up next

Depending on timing, brief Monopolistic Competition and then externalities and public goods.
